

Processes v/s Threads L-1.11

(14)

→ we are talking about multitasking platform

Process

- (i) system calls involved in process
- (ii) OS treats different process differently.
- (iii) different process have different copies of data, files, code.
- (iv) Context switching is slower
- (v) Blocking a process will not block another.
- (vi) Independent

If one thread is blocked, all are blocked

Threads

Threads (user level)

There is no system call involved

All user level threads treated as single task for OS.

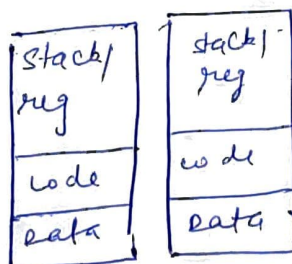

Threads share same copy of code and data

Context switching is faster

Blocking a thread will block entire process.

Interdependent.

If one parent process is blocked, child processes are unaffected.

fork()

Processes

1-1.12 User Level Threads v/s kernel level threads (15)

User Level Thread

- (i) User level threads are managed by user level library
- (ii) User level threads are typically fast
- (iii) Context switching is faster. (managed by library)
- (iv) If one user level thread perform blocking operation, then entire process gets blocked.

Because OS does not know about threading in user level process

kernel level thread

- kernel level threads are managed by OS system calls.
- kernel level threads are slower than user level.
- Context switching is comparatively lower. (because OS is invoked)

If one kernel level thread is blocked, no effect on others.

Process > KLT > ULT

~~~~~  
context switching time.

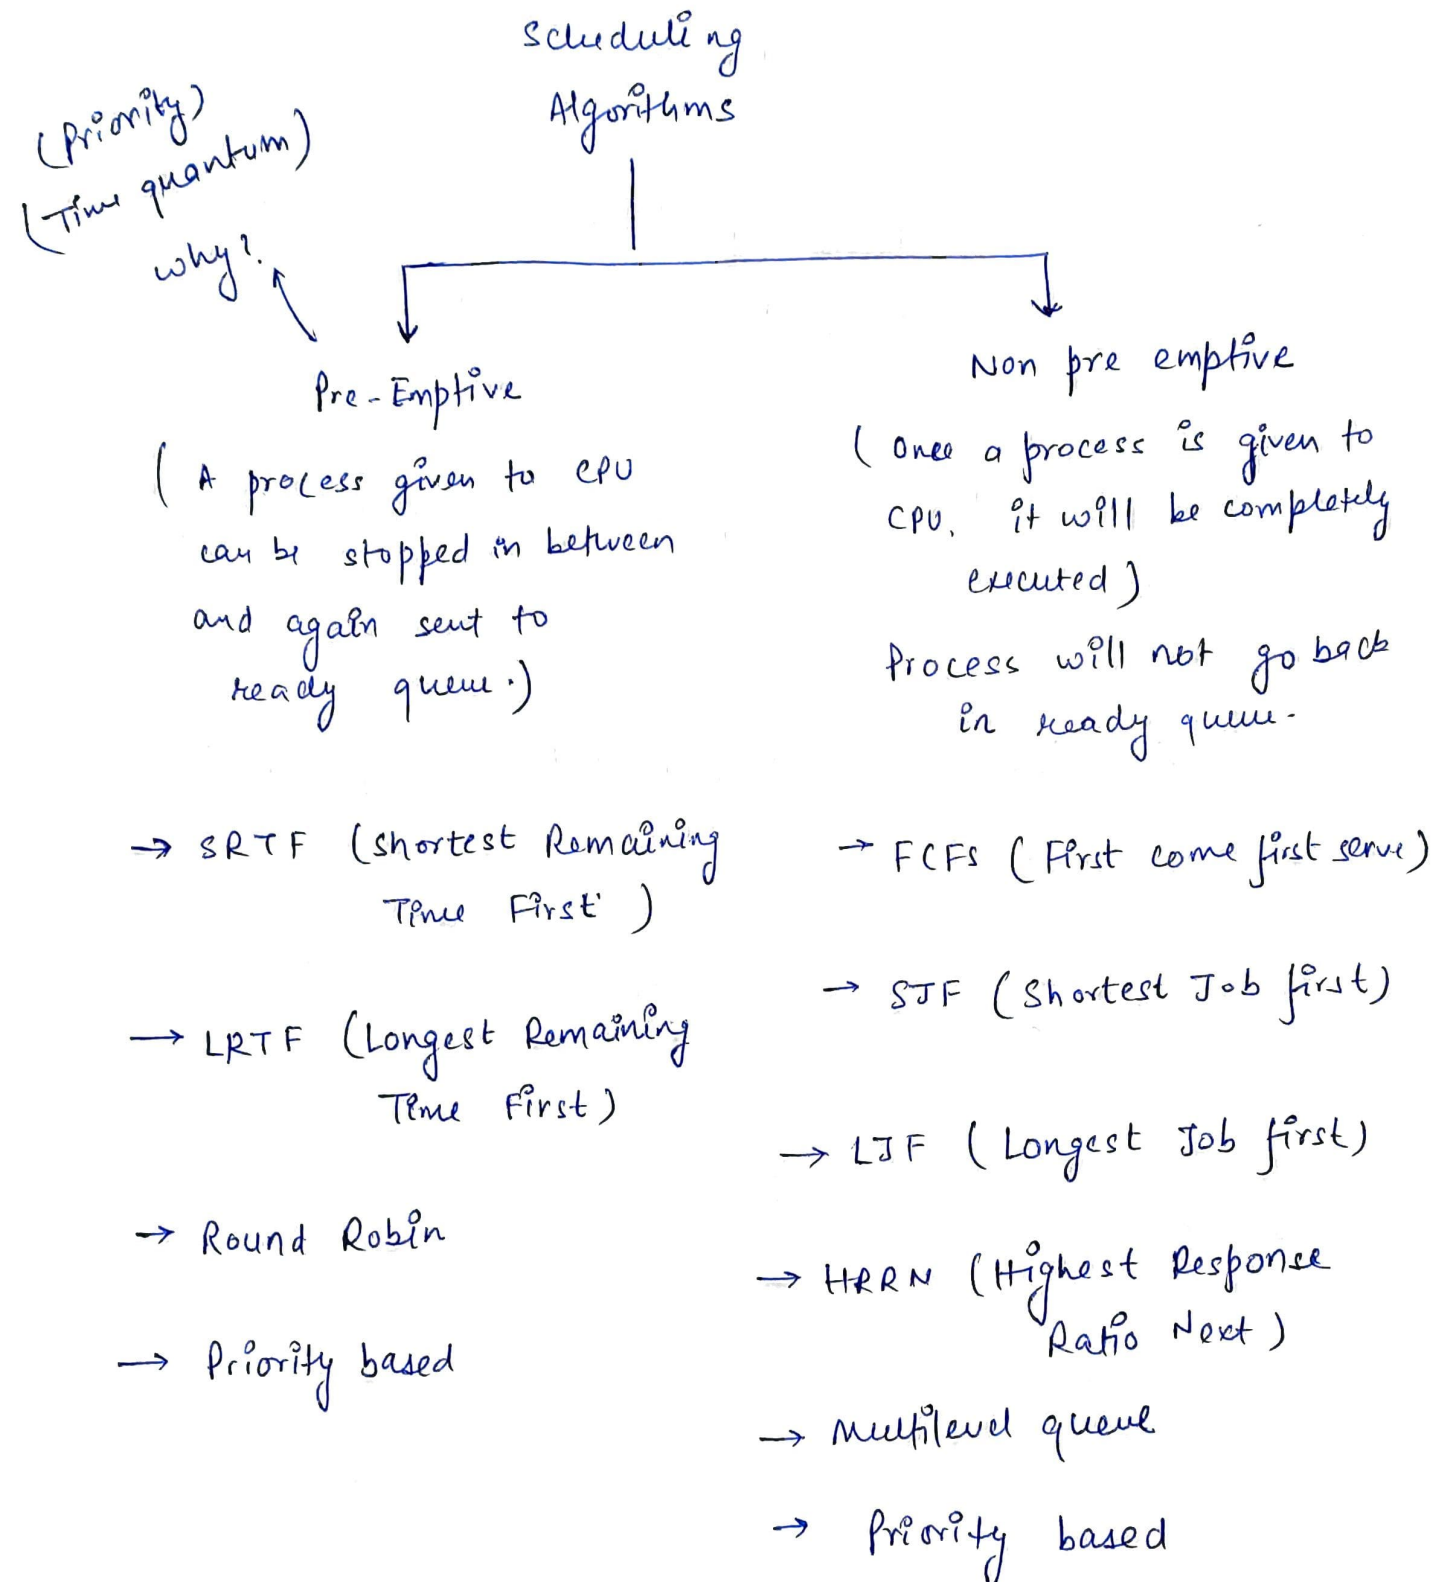

Nowadays, we use hybrid environment.

→ Threads always share code and data. That is why it is called lightweight.

~~##~~

↳ Algorithms to select processes from ready queue and giving it to CPU are called scheduling algorithms.

## # L-2.2 Times in CPU scheduling

- (i) **Arrival time** : The point of time at which process enters the ready queue or state.
- (ii) **Burst time** : Duration of time required by a process to execute on CPU.
- (iii) **Completion time** : Point of time at which process completes its execution.
- (iv) **Turn Around Time** :  $\{ \text{completion time} - \text{Arrival time} \}$
- (v) **Waiting time** :  $\{ \text{Turn Around time} - \text{Burst time} \}$
- CPU bound process  $\rightarrow$  time it takes to execute on CPU
- I/O bound  $\rightarrow$  time for I/O (goes into waiting time)
- (vi) **Response time** :  $\{ (\text{Time at which a process gets to CPU first time}) - \text{Arrival time} \}$
